

LETTER TO THE EDITOR

Reply to letter "Beta-blockers in acute coronary syndrome patients: The concept of 'gradient of benefit'"

Resposta à Carta «Beta-bloquantes no doente pós-SCA: o conceito de gradiente de benefício»

We would like to thank Fernando Montenegro Sá and João Morais for their interest in our paper.¹ Beta-blockers are indicated after ST-segment elevation myocardial infarction (STEMI) in patients with left ventricular ejection fraction (LVEF) $\leq 40\%$ (class I recommendation, level of evidence A) but in those with LVEF $> 40\%$ the benefit is not clear (class IIa, level B).² We agree that in patients in the 40-50% range beta-blockers appear more likely to help than to harm, due to their moderate probability of future events. The gradient of benefit means that beta-blockers should probably not

be used in very low risk STEMI,^{3,4} in which the risk of cardiovascular events is extremely small in the near future. In addition, beta-blockers should be avoided in high-risk patients in whom side effects will probably occur, as in those with hypotension, acute heart failure,⁵ or shock⁶ (Figure 1).

Further studies are needed to better identify STEMI patients who might benefit from beta-blockers, taking into consideration not only LVEF, but also other factors associated with prognosis that might improve with this treatment. For instance, endothelial dysfunction is common in STEMI⁷ and beta-blockers improve microvascular function.⁸ This is also the case with atrial fibrillation.^{9,10} Most studies of beta-blockers in STEMI were performed in an era when the rate of primary angioplasty was low and heart failure and mechanical complications were frequently seen.¹¹ The current scenario is different and extrapolation of previous data could lead to overuse of these drugs. In the Description of Acute Myocardial Infarction: Management, New Therapies and Evolution (DIAMANTE) registry, 86% of our

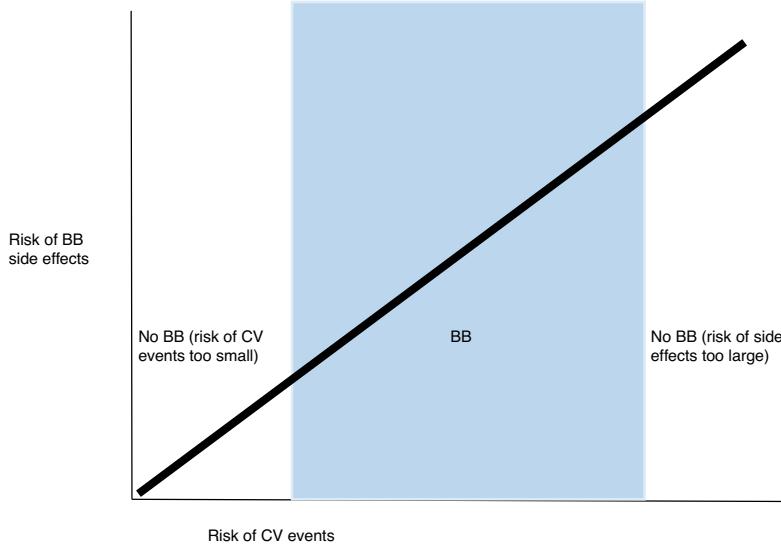

Figure 1 The gradient of benefit of beta-blockers (BB) according to the risk of future cardiovascular (CV) events and the risk of drug side effects in patients with ST-segment elevation myocardial infarction.

patients received beta-blockers.¹ Finally, regarding dosage, Mars et al.¹² have recently shown that target dose is not associated with cardiovascular outcomes, and Goldberger et al.¹³ even suggest that patients treated with 12.5–25% of the target dose may have enhanced survival compared with other doses.

Conflicts of interest

The authors have no conflicts of interest to declare.
